oxygen, obtaining O_2 from the environment is altogether more difficult and energy-intensive activity for marine animals than it is for air-breathers.

The mouth and gill cavity of fish operate like the vacuum pump in a fish tank. This ensures that water flows continuously across the gills and the maximum amount of oxygen is removed from the water with minimum effort.

Many small or inactive marine organisms such as larvae or barnacles can diffuse gases across their skin or waxy epidermis 'buds' in the water. Larger, more active species such as fish and crayfish have specialised breathing apparatus for collecting oxygen. The gills of fish, for example, consist of thousands of thin filaments, each with very fine ridges that provide a huge surface area for oxygen and carbon dioxide to pass quickly and efficiently to and from the blood.

Like humans, cetaceans such as whales breathe air. They fill their lungs with oxygen-rich air at the surface through their blowholes. Marine mammals can stay submerged for long periods because they have high blood volumes and large levels of oxygen-carrying pigments in their muscles, which act as oxygen stores.

DEPOSIT FEEDERS

Deposit feeders ingest sediment and extract organic matter from it. They are found in soft-bottomed areas such as mudflats and seagrass beds. Deposit feeders are important for recycling nutrients in the ecosystem.

GRAZERS

Grazers feed on algae and other organisms that grow on the seabed. They are found in rocky areas and seagrass beds. Grazers are important for controlling the growth of algae and other organisms.

Gills of animals (three examples) are shown here, illustrating both as a requirement for feeding and as a requirement for breathing.

The gills of animals (three examples) are shown here, illustrating both as a requirement for feeding and as a requirement for breathing.

Mussels

Mussels are bivalve molluscs with two shells, fed on the rock plankton found in seawater. Their gill filter out food particles from the seawater driven in by their beating, 'fan-like' cilia. The cilia and muscles pump the seawater particles to graze along the length of the gills where it is stored by a pair of lateral palps that collect material that proceeds to the mouth and where that it periodically spat out.

Kina

Kina (sea anemones) are sessile, creeping growing algae or anemone-like animals that live off rocks. Kina can eat almost anything, but have a preference for large brown algae such as the common kelp (*Laminaria*). Kina can taste the presence of this kelp chemically. They move in response to it, systematically forming large groups that can move down entire kelp forests, reaching 'harvest' of kelp beds. Such anemones have produced ecological impacts on the types and numbers of algae, fish and other organisms found on the reef.

Crayfish

Crayfish (decapod crustaceans) have a split, segmented body made up of two main sections. The mouth, located under the front section (cephalothorax), is surrounded by several pairs of specialised feeding appendages, which manipulate food before passing it to a pair of mouthparts (mandibles). During the day, crayfish move at night to feed. Sometimes, mandibles hang close to food, but adults may hang up to 10 cm away, occasionally pulling long distances (1 to 3 km) to feed food, and taking shelter to another site.

Crayfish prey on a wide range of invertebrates, including sea stars and kelp. Small prey are simply crushed and eaten but large invertebrates are especially taken and they break and the meat can be wrapped up. Crayfish use their front legs to eat around the mouth of large fish and scrape up the remains of their own shells.

Notes: The structure of a crayfish shows the structure of their own shells.

Shallow predators graze slowly over the reef, searching and eating their prey. The most interesting and slowest of these is the fish, *Dasyatis*, which will take prey a half its own length. With its slow, steady progress, it is very hard to see. It is very slow to get close. Its sense of touch is well developed. It will use its slow and steady progress to move like a long, thin fish moving to the side then a *Dasyatis* in attack mode. In the face of its prey, it will move its mouth to rapidly close the distance, sucking the prey in.

The third predatory type - the invertebrate predator - is known for its conventional shape, high mobility capacity and its long, narrow, and slow-moving. It is the most common predator on New Zealand rocky reefs.

ORIGINAL RESEARCH ARTICLE

A Framework for Mixed Reality Free-Choice, Self-Determined Learning

Claudio Aguayo^{a*}, Chris Eames^b and Thomas Cochrane^a

^aCentre for Learning and Teaching, Auckland University of Technology, Auckland, New Zealand; ^bSchool of Education, University of Waikato, Hamilton, New Zealand

*Received: 14 October 2019; Revised: 26 December 2019; Accepted: 8 January 2020;
Published: 9 March 2020*

In this article, we present a theoretical framework for mixed reality (MR/XR) self-determined learning to enhance ecological literacy in free-choice educational settings. The framework emerged from a research study in New Zealand which aimed to explore how learning experiences which incorporate mobile technologies within free-choice learning settings can be designed to enhance learner development of marine ecological literacy. An understanding of how mobile technology

Table 1. A framework for complementary mixed reality (XR) and free-choice learning education.

(1). Mobile learning considerations

- i. Mobile, immersive and real experiences should support and complement each other through a mixed reality approach (following current digital trends)
- ii. Mobile learning implementation and use (in free-choice education) must focus on bring your own device (BYOD), in part to manage the cost of technology.
- iii. Mobile learning opportunities should emphasise self-determined learning (heutagogy), so that the learning experience can unfold in unique ways for each learner based on their own motivations and needs.
- iv. User-informed design and co-creation should guide the design of mobile learning opportunities to promote meaningful learning.
- v. Mobile learning opportunities should be authentic to the context, integrated within and across learning areas and scaffolded for a clear learning pathway.
- vi. Mobile learning opportunities require access to technology (e.g. WIFI connectivity and IT infrastructure) and staff who are well prepared in the use of the technology and the pedagogy/heutagogy that can maximise learning.
- vii. Learners need prior training and exposure in the use of mobile learning resources (e.g. virtual reality) in order to be able to focus maximally on the learning intentions of their use.

(2). Pedagogy/heutagogy (teaching and learning principles)

- i. Focus should be placed in self-determined (heutagogical) learning, where the learning is guided by learners' motivations and needs.
- ii. The placement of the outside-the-classroom visit within a teaching unit is pedagogically important.
- iii. The structure of the outside-the-classroom visit is pedagogically and logistically important.
- iv. Pre-visit resources can help to sensitise learners and initiate connections to place (the visit site).
- v. Use of the mobile learning resources (virtual/immersive environments) should be designed to complement and not detract from sensory (embodied/haptic) experiences in the real environment.
- vi. The visit should allow freedom to experience but also have some focus to scaffold learning, and to promote interactions between learners (social learning).
- vii. Opportunities for learners to interact with both real and virtual/immersive learning environments increase learner autonomy and engagement.
- viii. Learning needs to be reinforced post-visit to deepen knowledge, clarify attitudes and support next learning steps.

(3). The learning context (in this case: Marine science and conservation)

The key concepts in the context that underpin the unit of teaching which includes mobile learning and education outside the classroom, for example (in this case):

- i. Marine reserves conserve the marine environment through protection, research and education.
- ii. Marine reserves protect biodiversity (e.g. range of species within the reserve).
- iii. Marine reserves provide social and/or cultural benefits (e.g. cultural practices).
- iv. Biodiversity is crucial for interdependence (e.g. food webs snapper/kina).
- v. Pollution threatens marine environments (e.g. sedimentation runoff, plastics).
- vi. Global warming is threatening marine environments (e.g. ocean temperature change and acidification).

(4). Learning objectives (in this case: Development of ecological literacy)

What you intend students/adult learners to be able to know and do in response to the teaching and learning through mobile learning and education outside the classroom/free-choice education.

- i. To develop ecological literacy about marine reserves, learners need to:
 - a. Gain knowledge of marine ecology and the impact of marine reserves (environmentally, socioculturally and economically) through authentic inquiry, system thinking and meaningful experiences
 - b. Demonstrate holistic thinking that views marine reserves as systems that connect the natural environment with society and its culture and economy
 - c. Reflect on their own and others' attitudes and values towards marine reserves
 - d. Be motivated and able to think critically, plan and take action in respect of marine reserves.

9. ACTIVITY THEORY AND ONLINE COMMUNITY EDUCATION FOR SUSTAINABILITY

When Systems Meet Reality

INTRODUCTION

Community Education for Sustainability (EfS) using Information and Communication Technology (ICT) tools and affordances (i.e., possibilities) bring together learning processes occurring within different interconnected dimensions in complex and unpredictable ways. Such complexity calls for the adoption of a systems thinking approach, where the focus is on the existing relationships between the different components composing the learning system.

By adopting a systems thinking approach, the design and implementation of ICT-based online learning systems can account for the ever-changing dynamic complexity that unfolds in multidimensional learning contexts. In this view, learning emerges when learning actors come together in a shared action, or inter-action, which is at the basis of social learning in community EfS using ICT tools. Here the learning process is regarded as an integral outcome of the whole learning system, as properties of systems can only be found as part of the 'whole' and not within its individual 'parts' or components. In this scenario, the role of online learning systems is to act as a facilitator of the learning process by actively promoting meaningful and culturally responsive interaction with community members that can lead to engagement in

(Aguayo, 2016)

Promoting community socio-ecological sustainability through technology: A case study from Chile

Claudio Aguayo¹ · Chris Eames²

© Springer Science+Business Media B.V. and UNESCO Institute for Lifelong Learning 2017

Abstract The importance of community learning in effecting social change towards ecological sustainability has been recognised for some time. More recently, the use of Information and Communication Technology (ICT) tools to promote socio-ecological sustainability has been shown to have potential in community education for sustainable development (ESD). The effective design and use of technology for community learning implies an understanding of a range of cross-dimensional factors including: socio-cultural characteristics and needs of the target

(Aguayo & Eames, 2017)

Key themes in mobile learning: Prospects for learner-generated learning through AR and VR

Claudio Aguayo, Thomas Cochrane, Vickel Narayan
Auckland University of Technology

This paper summarises the findings from a literature review in mobile learning, developed as part of a 2-year six-institution project in New Zealand. Through the development of a key themes codebook, we address selected key themes with respect to their relevance to learner-generated learning through emerging technologies, with attention to mobile augmented reality and mobile virtual reality. We see that these two current mobile learning affordances, complemented through relevant approaches to research and practice in mobile learning such as design-based research and connected social learning, are critical to reconceptualise learning through mobile devices. We conclude that mobile learning still requires the theories, methodologies, and practices of its own as a field. We also see a need for mobile learning to be conceptualised around ever-changing learning affordances and educational settings, rather than focusing on static structures such as content-delivery approaches, while embedding it within the scholarship of technology enhanced learning.

Introduction

Cook and Santos (2016) argue for the emergence of three aspects of mobile learning: the integration with social media for connecting learners and work-based practice, the use of design research to guide mobile learning implementation, and learner-generated content and contexts in learning. Mobile learning (re)conceptualised around what learners can do and create through mobile affordances (the range of possibilities offered by mobile technology) that is learner-generated content and context or technology

USING MOBILE LEARNING IN FREE-CHOICE EDUCATIONAL SETTINGS TO ENHANCE ECOLOGICAL LITERACY

Claudio Aguayo
Auckland University of Technology
New Zealand

CHRIS EAMES
The University of Waikato
New Zealand

Abstract

This article presents the case for using mobile technologies to facilitate the integration of classroom and outside-of-classroom learning experiences designed to enhance the ecological literacy of primary school students and their parents. There is growing evidence supporting the transformative potential of mobile learning technologies and tools within education settings to deliver meaningful learning experiences. We argue here that this potential could extend to integrating learning between the classroom and education outside the classroom (EOTC). We further argue that this mobile learning potential can mediate learning between students and their parents, visitors and educators at free-choice learning settings. We situate our argument within learning to enhance ecological literacy and call for studies that can consider the possibilities offered by mobile technology and related pedagogical frameworks, the reinforcement of learning experiences post a visit to a free-choice setting, and the integration with hands-on and non-technology mediated learning instances. Here we present some key theoretical considerations as a prelude to a study being funded by the Teaching and Learning Research Initiative to examine these possibilities.

Kia ora team. I'm Ali, digital media developer at AppLab and PhD candidate at AUT, researching 3D UX/IxD in Mixed Reality. I will be working on the 360 videos and the Augmented Reality section of the Explora app. I will be helping with the technical aspect of the project while working with Claudio, Josh, and James. Looking forward to meeting you all online and discuss the project further.

Hello everyone! I'm Carolina, marine biologist and dedicated to marine education. At this team, my role is to supervise the big project (the digital part and beyond!) and to make sure that everything works. I was lucky enough to visit NZ and got the chance to meet some of you (or I think all of you!). Thank you for the work already done. Let's keep it flowing like the ocean!!

In this article, we present a theoretical framework for mixed reality (MR/XR) self-determined learning to enhance ecological literacy in free-choice educational settings. The framework emerged from a research study in New Zealand which aimed to explore how learning experiences which incorporate mobile technologies within free-choice learning settings can be designed to enhance learner development of marine ecological literacy. An understanding of how mobile technology can be integrated into the teaching and learning of sustainability education that

The background of the slide features a series of horizontal, wavy bands in various shades of blue, creating a layered, water-like effect.
