4 Abstract

5 Purpose - This research aims to examine the impact of metaverse experiences on customers'
6 offline behavioral intentions: How do customers' visits to a hospitality business's virtual
7 property in the metaverse affect their intentions to visit the physical property in the real
8 world?

9 Design/methodology/approach - Based on the general learning model and social cognitive
10 theory, this research hypothesizes the positive impact of metaverse experiences on customers'
11 visit intentions and explores two boundary conditions for positive impact: user–avatar
12 resemblance and servicescape similarity. Two experimental studies were conducted.

13 Findings - Metaverse experience has a significant impact on customers' visit intentions, and
14 this impact is moderated by user–avatar resemblance and servicescape similarity.

15 Research implications – This research addresses the call for empirical studies regarding the
16 effects of metaverse experience on people's behavioral intention.

17 Originality - As one of the earliest empirical studies on the marketing effects of the
18 metaverse, this research provides a basis for future metaverse studies in the hospitality field.

19 Article classification: Research paper

20
21 *Keywords:* Metaverse; general learning model; social cognitive theory; avatar; servicescape.

1. Introduction

Many hospitality businesses are adopting the metaverse trend for marketing purposes (Ghare, 2022). Some leading brands have already established plans for metaverse marketing campaigns (Wood, 2022): restaurants (McDonald's), hotels (Ritz Carlton), entertainment (Walt Disney), and more. After being selected as one of the top trends that will reshape the hospitality industry, metaverse marketing is rapidly growing in popularity in the industry (EHL Insights, 2022). The recent COVID-19 pandemic has encouraged people to pay attention to virtual experiences in the metaverse to satisfy their wanderlust. According to Gartner's report (2021), about one in three people is expected to spend over two hours a day in the metaverse for entertainment by 2027. The potential business benefits of metaverse marketing are being actively discussed in the hospitality industry (Gursoy *et al.*, 2022).

The metaverse is defined as a virtual world where our avatars and those of other people in the world come together for various purposes, such as working, shopping, attending classes or events, and travelling (Koo *et al.*, 2022). As an alternate reality, the metaverse incorporates a range of technologies to parallel the real world (e.g., a 5G network for real-time interaction, augmented or virtual reality for multisensory interaction, and non-fungible tokens for the transaction of digital and physical assets) (Hollensen *et al.*, 2022). As it blurs the line between the virtual and real worlds, it is expected that what we do in the metaverse does not end in the virtual world but affects how we behave in the real world (Buhalis *et al.*, 2023). The expectation that the metaverse experience affects visitors' offline behavior is leading hospitality businesses to adopt specific strategies for metaverse marketing.

By building a digital twin of its property in the metaverse, a hospitality business enables people to virtually experience the service that they can be offered when they visit the business's physical property. With such a strategy, a hospitality business encourages virtual customers to be actual customers in the real world. Specifically, a hospitality business allows

1
2
3 47 people to undertake a range of activities on its virtual property that are feasible in the real
4
5 48 world, to induce them to visit the physical property (Lee and Kim, 2022). A restaurant
6
7 49 encourages guests to order food in the business's virtual branch in the metaverse and receive
8
9 50 it in its physical branch in the real world (Ampountolas *et al.*, 2023). By allowing customers
10
11 51 to enjoy a rooftop lounge on its virtual property, a hotel hopes to boost their desire to visit its
12
13 52 physical property to enjoy the amenities (Kilburn, 2022). When hosting a concert in the
14
15 53 metaverse, the organizer allows people to see an artist very closely or take pictures with the
16
17 54 artist to ensure the virtual attendees have an increased intention to visit the artist's actual
18
19 55 concert in the real world (Savage, 2021).

20
21
22
23
24 56 Although a hospitality business strives to influence customers' offline behavioral
25
26 57 intentions through the metaverse experience, the precise impact of this experience remains
27
28 58 uncertain. Recent marketing studies, spanning beyond the hospitality sector, have emphasized
29
30 59 the need to explore the connection between the metaverse experience and customers' offline
31
32 60 behavioral intentions (Hollensen *et al.*, 2022; Kim, 2021; Wiederhold, 2022). However,
33
34 61 existing hospitality and tourism research primarily discusses the metaverse's impact on
35
36 62 customers' real-world behavior in a conceptual manner (Buhalis *et al.*, 2023; Go and Kang,
37
38 63 2023; Gursoy *et al.*, 2022; Koo *et al.*, 2022; Mladenović *et al.*, 2023). Although empirical
39
40 64 studies on the metaverse experience in various contexts, such as retail shopping and
41
42 65 promoting pro-environmental attitudes, have been conducted (Chan *et al.*, 2023; Jafar *et al.*,
43
44 66 2023; Kim *et al.*, 2023; Xi *et al.*, 2023), the majority of studies have focused on individuals'
45
46 67 attitudes or behavioral intentions within the metaverse. Despite the metaverse's rising
47
48 68 popularity as the next paradigm in the hospitality industry, its implications for marketing
49
50 69 remain unknown (Cai *et al.*, 2024; Hazan *et al.*, 2022; Zaman *et al.*, 2024).

51
52
53
54
55
56 70 This research aims to investigate the impact of the metaverse experience on
57
58 71 customers' offline behavioral intentions in the hospitality context. Considering the metaverse
59
60

72 marketing strategies employed by hospitality businesses, the research addresses the following
73 question: How does a customer's visit to a hospitality business's virtual property in the
74 metaverse influence their intention to visit its physical property in the real world?
75 Additionally, the research explores two potential boundary conditions for the relationship
76 between the metaverse experience and behavioral intention: Is the impact of the metaverse
77 experience on customers' offline behavioral intentions moderated by the extent to which an
78 avatar resembles the customer, and by the similarity between a business's virtual property
79 and the physical one in terms of servicescape?

80 Drawing on the general learning model (GLM) (Buckley and Anderson, 2012) and
81 social cognitive theory (Bandura, 1977), this research hypothesizes that (1) the metaverse
82 experience increases customers' intentions to visit a hospitality business's physical property
83 in the real world, and (2) the effect of the metaverse experience becomes more pronounced
84 when the experience is similar to the real situation (i.e., when customers use avatars
85 resembling their own appearance and when virtual properties have the same servicescape as
86 physical ones). To achieve these objectives, two studies were conducted in a café context.

87

88 2. Research Background

89 Although the metaverse is not yet clearly defined, it generally refers to a parallel
90 reality where people, as avatars, can work, play, communicate, and "live" (Needleman,
91 2021). The term, a combination of the words "meta" and universe, was first coined in a piece
92 of science fiction written by Neal Stevenson, *Snow Crash*, in 1992. The virtual world concept
93 has been realized and developed through four major transitions from text-based interactive
94 games (e.g., AberMud, DikuMud) to virtual open worlds (e.g., Active World, Onlive
95 Traveler), massive multiplayer online games (e.g., Second Life, Minecraft), and immersive
96 virtual environments on smart mobiles and wearables (e.g., Pokémon GO, VRChat) (Duan *et*

1
2
3 97 *al.*, 2021). Every transition was driven by the advent of enabling technologies (e.g., Internet,
4
5 98 3D graphics, extended reality, blockchain, and so on) (Wiederhold, 2022), and now several
6
7 99 metaverse platforms are considered to almost realize Stevenson's imaginings (e.g.,
8
9
10 100 Decentraland, Sandbox, Roblox, and Zepeto) (Dwivedi *et al.*, 2022).

11
12 101 The metaverse has several characteristics that distinguish it from video games that
13
14 102 closely imitate the real world, platforms that leverage virtual environments, and other related
15
16 103 concepts (Go *et al.*, 2021; Lee *et al.*, 2021). First, people can make digital creations inside the
17
18 104 metaverse, ranging from a piece of textual content to a virtual item, an event, a building, or a
19
20 105 city. Also, people can interact with objects, places, and others in various ways (e.g.,
21
22 106 purchasing or selling an artwork, taking a selfie at a popular spot in a city, and travelling with
23
24 107 friends) (Go *et al.*, 2021). These differentiate the metaverse from social virtual reality
25
26 108 platforms, which limit the ability to make digital creations and provide limited options for
27
28 109 interactions (Lee *et al.*, 2021). Second, the metaverse is a perpetual space. Even when you log
29
30 110 out of the metaverse, the virtual world keeps changing based on others' activities or
31
32 111 interactions (e.g., launching a new event, building a new store, selling a real estate asset)
33
34 112 (Goldston *et al.*, 2022). As a sustained and persistent virtual world, the metaverse does not
35
36 113 vanish, regardless of whether you log into the world or not. This differentiates the metaverse
37
38 114 from the virtual spaces for games, events, classes, and so on, which disappear after the focal
39
40 115 activities (Lee *et al.*, 2021). Last, the metaverse coexists and interoperates with the real
41
42 116 world. The metaverse comprises digital twins of their physical counterparts, including people
43
44 117 and their motions or behaviors, objects and their functions, business properties, and even
45
46 118 cities (Lv *et al.*, 2022). The digital copy of the physical environment operates based on social
47
48 119 norms, economies, and laws, which are analogous to the real world's existing systems (Kicks,
49
50 120 2021). In a parallel reality, people have a daily life as they do in the real world, and their
51
52 121 activities in the metaverse affect their behavior in the real world (Go *et al.*, 2021). This
53
54
55
56
57
58
59
60

1
2
3 122 differentiates the metaverse from almost all other virtual platforms, which have lower levels
4
5 123 of extension of reality (Lee *et al.*, 2021).
6
7

8 124 The last characteristic of the metaverse drives hospitality businesses to expect an
9
10 125 impact of virtual experiences on people's offline behavior and, further, to adopt specific
11
12 126 strategies for metaverse marketing. A hospitality business offers replication of real service
13
14 127 experiences to people in the metaverse in order to increase their likelihood of visiting the
15
16 128 business's physical property for real experiences (Lee and Kim, 2022). Domino's Pizza
17
18 129 enables customers to order pizza through the digital twin of its ordering kiosk in
19
20 130 Decentraland and encourages them to visit its physical branch as a result of the virtual order
21
22 131 experience (Canter, 2022). An emerging hotel brand in the United Kingdom, LEVEN, plans
23
24 132 to launch virtual fitness and meditation sessions at its virtual property in the metaverse, which
25
26 133 are linked to the sessions taking place at its physical property in the real world, to transform
27
28 134 virtual guests into actual ones (Kilburn, 2022). When hosting a virtual concert in Roblox, the
29
30 135 management agency for pop star Zara Larsson sold the outfits, hairstyles, and dance moves of
31
32 136 the artist to make virtual attendees feel more connected to the artist and, subsequently,
33
34 137 increase their intention to attend a real concert in the future (Savage, 2021). With a similar
35
36 138 objective, the management agency of Blackpink, a South Korean girl group, hosted a virtual
37
38 139 fansign in Zepeto and allowed virtual attendees to connect with each member of the group via
39
40 140 avatars in various ways (e.g., getting an autograph or taking a selfie together) (Song, 2021).
41
42
43
44
45
46

47 141 The potential influence of metaverse experiences on customers' behavioral intentions
48
49 142 in the real world finds support in the GLM proposed by Buckley and Anderson (2012). An
50
51 143 extension of the general aggression model, which explains the impact of a violent stimulus on
52
53 144 an individual's antisocial behavior (Bushman and Anderson, 2002), the GLM posits that all
54
55 145 information in the surrounding environment can serve as a learning opportunity, influencing
56
57 146 an individual's present internal state (comprising cognition, affect, and arousal) and guiding
58
59
60

1
2
3 147 behavioral responses (Buckley and Anderson, 2012). According to GLM's assumptions,
4
5 148 various stimuli, such as media or games, can trigger individual behavior by affecting their
6
7 149 internal state (Buckley and Anderson, 2012). For instance, GLM suggests that consuming
8
9 150 media content offers significant learning opportunities. Studies have explored the impact of
10
11 151 media content consumption on behavior, showing that engaging with prosocial content in
12
13 152 books, music, and TV programs increases individuals' intention to engage in prosocial
14
15 153 behavior (Hahn *et al.*, 2022; Ruth, 2017; Zhang, 2021). GLM has also been applied to virtual
16
17 154 experiences, such as specific activities conducted through avatars in virtual games. Research
18
19 155 indicates that playing violent games results in corresponding real-world behavior, while
20
21 156 engaging in healthy activities through avatars positively influences players' health-related
22
23 157 behavior in the real world (Rheu *et al.*, 2020; Wu *et al.*, 2023).

28 158 A crucial theoretical component of GLM, social cognitive theory, further elaborates
29
30 159 on the impact of learning experiences on individual behavior. The theory introduces three
31
32 160 boundary conditions that enhance the influence of learning experiences on behavioral
33
34 161 reactions: the extent to which an individual is rewarded for the learned behavior (i.e.,
35
36 162 reinforcement); the extent to which an individual has the ability to do the learned behavior
37
38 163 (i.e., self-efficacy); and the extent to which the role models are similar to an individual in
39
40 164 terms of appearance (i.e., identification) (Bandura, 1977). Focusing on the moderating role of
41
42 165 identification in virtual experiences, the theory argues that individuals are more likely to
43
44 166 replicate learned behaviors when their virtual representation (e.g., avatar) resembles them and
45
46 167 when the virtual space mirrors their surroundings. Given that the metaverse experience shares
47
48 168 similarities with virtual experiences, involving the use of avatars for various activities in a
49
50 169 virtual environment, we anticipate that GLM and social cognitive theory arguments are
51
52 170 applicable. Engaging in specific activities in the metaverse is expected to lead individuals to
53
54
55
56
57
58
59
60

1
2
3 171 replicate similar activities in the real world, with the impact being more pronounced when the
4
5 172 individual's avatar resembles them and their surroundings.

6
7
8 173 Many hospitality businesses have either implemented or plan to adopt metaverse
9
10 174 marketing, expecting the virtual experience to alter customers' behavior in the real world
11
12 175 (Lee and Kim, 2022). Also, recent conceptual research on metaverse marketing has proposed
13
14 176 the use of metaverse experiences to modify customers' attitudes and behaviors in the real
15
16 177 world (Buhalis *et al.*, 2023; Gursoy *et al.*, 2022; Kim, 2021; Koo *et al.*, 2022). However, the
17
18 178 potential impact of metaverse experiences on customers' offline behavioral intentions has not
19
20 179 been tested, and thus, empirical research investigating the impact is being called for by both
21
22 180 researchers and practitioners (Hazan *et al.*, 2022; Hollensen *et al.*, 2022; Wiederhold, 2022).

23
24
25
26 181 Numerous empirical studies have explored the effects of virtual travel experiences on
27
28 182 customers' behavioral reactions, offering insights that can be applied to discussions on
29
30 183 metaverse experiences (Kim *et al.*, 2020a). However, the vast majority of these studies
31
32 184 focused on experiences mediated by virtual reality. Consequently, their findings may present
33
34 185 challenges in directly extrapolating implications for the relationship between metaverse
35
36 186 experiences and customers' behavioral intentions. Given this background, this research aimed
37
38 187 to address the knowledge gap by examining the impact of metaverse experience on
39
40 188 customers' offline behavioral intentions in the hospitality context. Specifically, this research
41
42 189 tests how customers' visits to a hospitality business's virtual property in the metaverse affect
43
44 190 their intention to visit its physical property in the real world. Furthermore, to further
45
46 191 understand the relationship between the metaverse experience and behavioral intentions, this
47
48 192 research explored two potential boundary conditions for the relationship: the extent to which
49
50 193 an avatar resembles its user in terms of appearance and the extent to which the servicescape
51
52 194 of a virtual property is similar to that of a physical one.

53
54
55
56
57
58
59
60

196 3. Research Model and Hypotheses Development

197 Drawing on the GLM (Buckley and Anderson, 2012) and social cognitive theory
198 (Bandura, 1977), we developed the conceptual framework and research hypotheses (Figure
199 1). The GLM posits that virtual experiences, such as playing a virtual game, serve as learning
200 opportunities that can influence an individual's internal state and behavior (Buckley and
201 Anderson, 2012). Consequently, the GLM is frequently employed to investigate the impact of
202 virtual experiences on individual behavioral reactions. According to the GLM, virtual
203 experiences lead individuals to perceive their virtualized representation (e.g., avatars) as
204 themselves and integrate into the environment where they are engaged (Bailey and Bailenson,
205 2017). This sense of presence primes individuals with the actions performed during the
206 virtual experience, influencing them to replicate similar behaviors in the real world (Bushman
207 and Anderson, 2002).

208 [Figure 1]

209 In a study by Yin *et al.* (2022), a prosocial virtual game was considered a learning
210 stimulus based on the GLM, revealing that individuals tended to use prosocial words more
211 frequently after playing the game. Conversely, Wu *et al.* (2023) focused on unethical
212 behavior in a virtual game, demonstrating that engaging in such behavior in the game
213 increased the likelihood of individuals engaging in similar behavior in the real world.
214 Applying the GLM argument within the context of virtual experiences, we anticipate that the
215 metaverse experience will influence customers' behavioral intentions. Specifically, we
216 hypothesize that customers' visits to the virtual property of a hospitality business in the
217 metaverse will heighten their intention to visit the business's physical property in the real
218 world.

219

1
2
3 220 *Hypothesis 1: The experience of visiting a hospitality business's virtual property in the*
4
5 221 *metaverse increases a customer's intention to visit the business's physical*
6
7 222 *property in the real world.*
8
9

10 223

11
12 224 The social cognitive theory delineates how the impact of virtual experience on an
13
14 225 individual's behavior can be nuanced by factors such as reinforcement, self-efficacy, and
15
16 226 identification (Bandura, 1977). According to the GLM, virtual experience influences people's
17
18 227 offline behavior by immersing them in a virtualized scenario (Bushman and Anderson, 2002).
19
20 228 The social cognitive theory further posits that this immersion is more likely under specific
21
22 229 conditions, enhancing the impact of virtual experience on individuals' offline behavior
23
24 230 (Bandura, 1977). These conditions include situations where individuals' behavior in the
25
26 231 virtualized setting is rewarded (Hahn, 2022), when they perceive virtual actions as easy to
27
28 232 replicate in the real world (Alvarez-Risco *et al.*, 2022), and when their virtualized
29
30 233 representation (e.g., avatars) closely resembles their actual selves (Rheu *et al.*, 2020).
31
32

33
34 234 Among these conditions, identification holds particular relevance in the literature
35
36 235 when virtual experience is used as a learning stimulus, given the central role of avatars in the
37
38 236 experience (Kim, 2021). The increased impact of virtual experiences on individuals' offline
39
40 237 behavior due to the greater similarity between avatars and users' appearances has been
41
42 238 explored in various contexts. For instance, Navarro *et al.* (2022) observed that participants
43
44 239 exposed to avatars wearing sports clothes with their faces had higher cardiac frequency than
45
46 240 those exposed to stranger faces. Similarly, Koulouris *et al.* (2020) conducted experiments
47
48 241 where participants engaging in exercise via a virtual reality game using avatars customized to
49
50 242 resemble themselves were more inclined to exercise regularly than those using non-
51
52 243 customized avatars. Applying the identification aspect of social cognitive theory to the
53
54 244 current research, the experience of visiting a hospitality business's virtual property in the
55
56
57
58
59
60

1
2
3 245 metaverse is expected to significantly increase customers' intentions to visit its physical
4
5
6 246 property when people use avatars customized to resemble themselves. Specifically, we
7
8 247 hypothesize that customers' visits to the virtual property of a hospitality business in the
9
10 248 metaverse will more substantially boost their intention to visit the business's physical
11
12 249 property in the real world when there is a high level of user–avatar resemblance.

13
14
15 250

16
17 251 *Hypothesis 2: Customers' intentions to visit a business's physical property after a metaverse*
18
19 252 *experience will be higher when a customer uses an avatar customized to*
20
21 253 *resemble themselves.*

22
23
24 254

25
26 255 Several recent studies grounded in social cognitive theory have expanded the concept
27
28 256 of identification to include the similarity between the environment in a learning stimulus and
29
30 257 an individual's surroundings. It is argued that a learning stimulus exerts a greater impact on
31
32 258 an individual's behavioral reaction when they find themselves in a situation similar to that
33
34 259 depicted in the stimulus (Scavarelli *et al.*, 2021). Discussing the potential of virtual reality in
35
36 260 education, Hernandez-Pozas and Carreon-Flores (2019) advocated for a virtual space that
37
38 261 mirrors the students' study environment, emphasizing the importance of such similarity for
39
40 262 enhancing the learning effect. Similar arguments were supported in the work of Behnamnia *et*
41
42 263 *al.* (2020), who demonstrated that a digital game-based learning program for preschool
43
44 264 children led to the repetition of virtualized learning in the real world by creating a similarity
45
46 265 between the virtual and usual learning spaces. Building upon this empirical evidence, we
47
48 266 hypothesize that the impact of the metaverse experience on customers' visit intentions is
49
50 267 moderated by the similarity between a hospitality business's virtual property and the physical
51
52 268 one in terms of servicescape (servicescape similarity hereafter). Specifically, we propose that
53
54 269 customers' visits to the virtual property of a hospitality business in the metaverse will
55
56
57
58
59
60

270 significantly increase their intention to visit the business's physical property in the real world
271 when there is a high level of servicescape similarity.

272

273 *Hypothesis 3: Customers' intentions to visit a business's physical property after a metaverse*
274 *experience will be higher when the virtual property has the same servicescape*
275 *as the physical property.*

276

277 We further predicted an interaction effect between user–avatar resemblance and
278 servicescape similarity in the metaverse experience on customers' visit intentions.
279 Considering that identification through user–avatar resemblance is more obvious for the
280 metaverse experience, the effect of servicescape similarity on customers' visit intentions was
281 expected to be stronger only when a customer uses an avatar customized to resemble
282 themselves. When the avatar in the virtual world is different from the customer's actual
283 appearance, the metaverse experience is expected to be very low in terms of mental
284 simulation and meaningful engagement (Hilken *et al.*, 2022).

285

286 *Hypothesis 3a: The main effect of servicescape similarity on customers' visit intentions will*
287 *be stronger when a customer uses an avatar customized to resemble*
288 *themselves. Conversely, the main effect of servicescape similarity on*
289 *customers' visit intentions will be weaker when a customer uses an avatar*
290 *customized to be dissimilar themselves.*

291

292 **4. Methodology**

293 The four hypotheses were examined through two studies employing an experimental
294 design within a café context. Study 1 was executed to assess H1, aiming to determine

1
2
3 295 whether participants who virtually experienced a café through the metaverse exhibited a
4
5
6 296 higher intention to visit the actual café compared to those who did not undergo such an
7
8 297 experience. Study 2 was conducted to investigate H2, H3, and H4, all within the same café
9
10 298 context. We tested H2 by examining whether the participants who visited a café's virtual
11
12 299 property using avatars that resembled their appearance had a higher intention to visit the
13
14 300 café's real property than those who visited the same virtual property using avatars that do not
15
16
17 301 resemble their appearance. On the other hand, we targeted three cafés that are different in
18
19 302 terms of servicescape similarity: 1) a café whose virtual property's servicescape is similar to
20
21 303 real property's; 2) a café whose virtual property's servicescape is better than real property's;
22
23 304 and 3) a café whose virtual property's servicescape is worse than physical property's. The
24
25
26 305 participants visited the virtual property of one of the three cafés. To test H3, we compared the
27
28 306 three groups in terms of the intention to visit the focal café's real property. Finally, we
29
30 307 investigated the interaction between two factors in H4 as well.

31
32
33 308 Of the several world-famous metaverse platforms, Zepeto was used in this research
34
35 309 for several reasons, which is the biggest metaverse platform in Asia in terms of the number of
36
37 310 users (Oi, 2021). First, Zepeto is famous for its avatar-editing function, which enables users
38
39 311 to customize their avatars (Davies and Junga, 2022). Although it is difficult to customize
40
41 312 avatars to reflect users' appearances in detail on other metaverse platforms due to the semi-
42
43 313 standardized avatar system, Zepeto provides a higher degree of freedom in customizing
44
45 314 avatars (Park and Kim, 2022) (Figure 2). This allowed us to examine the moderating impact
46
47 315 of user–avatar resemblance on the relationship between metaverse experience and customers'
48
49 316 offline behavioral intentions.

50
51
52
53 317 [Figure 2]

54
55
56 318 Lastly, both high and low servicescape similarity are available on Zepeto. Although
57
58 319 most hospitality brands' virtual properties are designed differently from their physical
59
60

320 properties on other metaverse platforms, both differently and similarly designed virtual
321 properties are available on Zepeto (Park, 2022) (Figure 3). This allowed us to examine the
322 moderating effect of servicescape similarity on the relationship between metaverse
323 experience and customers' offline behavioral intentions.

[Figure 3]

5. Study 1

327 We tested H1 by investigating the influence of metaverse experience on customers'
328 offline behavioral intentions within the context of a café. The experiment involved comparing
329 participants who virtually experienced a specific café in the metaverse with those who did
330 not, with a focus on their intention to visit the café in the real world.

5.1. Design, procedure, and stimuli

333 Participants were randomly assigned to either the without-metaverse or with-
334 metaverse experience conditions in a between-subjects design. Those in the without-
335 metaverse condition watched a short video showcasing the café, whereas those in the with-
336 metaverse condition watched the same video and additionally visited the virtual version of
337 the café on Zepeto. Subsequently, both groups completed a survey.

338 We selected a café in South Korea, *SameE*, which had established a virtual property
339 on Zepeto. The virtual property shared the same name as the physical one, and its
340 servicescape, encompassing exterior, interior, food and beverage, and goods, closely
341 resembled that of the physical property (Figure 3). Participants in the with-metaverse
342 experience condition virtually explored *SameE* through Zepeto for approximately 5 minutes
343 using their smart devices, under the guidance and observation of a research assistant. To
344 ensure comparability in exposure time to content about *SameE*, we presented the 5-minute

345 video to the without-metaverse experience group and the shortened 1-minute version to the
346 with-metaverse group. A total of 120 undergraduate and graduate students in Hong Kong
347 participated, receiving bonus points of coffee as compensation.

348 Data cleaning involved removing responses from participants who had previously
349 watched the video and those who had visited *SameE* before. Additionally, participants who
350 did not watch the given video were filtered out based on the time spent watching and a
351 validity check question. Consequently, 107 participants (53 in the without-metaverse and 54
352 in the with-metaverse groups) were included for further analysis. A power analysis using the
353 G*Power program ($w = 0.25$, power $(1 - \beta) = 0.8$, $\alpha = 0.05$) confirmed that our sample size
354 exceeded the minimum required for analysis (minimum sample size = 51 per condition).
355 Thus, our sample was deemed sufficiently large for subsequent analysis (Faul *et al.*, 2007).

357 5.2. Measures and analysis

358 Customers' offline behavioral intentions were measured with four items drawn from
359 An *et al.* (2021). All measures used a 5-point Likert scale (1 = definitely not, 5 = absolutely).
360 The four items were highly correlated ($\alpha = 0.85$), and their mean scores were used for further
361 analyses. As participants watched a video about *SameE*, their intention to visit the café might
362 be influenced by their perceptions of the video. Additionally, their preferences or evaluations
363 of the café could introduce confounding factors. To address this, we measured participants'
364 perceptions of the video, preferences, and evaluations of the café, employing measurement
365 items derived from relevant previous research (Byun and Jang, 2015; Das, 2014). The
366 measurement items exhibited high correlations ($\alpha = 0.79$ for video perception, $\alpha = 0.75$ for café
367 preference, and $\alpha = 0.77$ for café evaluation). The mean scores of these items were utilized as
368 three control variables in subsequent analyses to mitigate the confounding impact of

369 participants' perceptions on their visit intention. With the above-mentioned measures, we
370 conducted a one-way between-subjects ANOVA with a covariate.

371 372 5.3. Results and discussion

373 The demographic details of the participants are provided in the Appendix. The results
374 of a one-way between-subjects ANOVA with a covariate revealed that participants who
375 experienced the virtual version of *SameE* on Zepeto exhibited significantly higher visit
376 intentions compared to those who did not visit the virtual café ($M_{\text{with-metaverse}} = 3.16$, $SD =$
377 0.96 vs. $M_{\text{without-metaverse}} = 2.46$, $SD = 0.93$; $F(1, 104) = 14.94$, $p < 0.001$, $\eta^2 = 0.12$) (Figure
378 4). Study 1 demonstrated a positive impact of visiting a virtual property in the metaverse on
379 the intention to visit the real property within a café context. Engaging in a virtual visit to a
380 café through the metaverse increased individuals' willingness to visit the actual café, thereby
381 supporting H1. These findings align with prior research indicating that certain activities in
382 virtual environments can influence individuals' intentions to engage in similar behavior in the
383 real world (Wu *et al.*, 2023; Yin *et al.*, 2022). Moreover, these empirical results substantiate
384 the arguments made in conceptual hospitality research regarding the impact of metaverse
385 experiences on customers' offline behavior (Buhalis *et al.*, 2023; Gursoy *et al.*, 2022; Koo *et*
386 *al.*, 2022).

387 [Figure 4]

389 6. Study 2

390 We examined the main effects of user–avatar resemblance (H2) and servicescape
391 similarity (H3) as well as their interaction effect (H4) on the relationship between metaverse
392 experience and customers' offline behavioral intentions in Study 2. We conducted an
393 experiment in a café context.

394

395 *6.1. Design, procedure, and stimuli*

396 In this study, participants were randomly assigned to one of four experimental
397 conditions using a between-subjects design: 2 (user–avatar resemblance: high vs. low) × 2
398 (servicescape similarity: high vs. low). All participants were instructed to watch a brief video
399 showcasing a physical café and then to visit the virtual property of the same café on Zepeto.
400 Initially, we manipulated user–avatar resemblance, where participants used avatars
401 resembling their appearance (high resemblance) or avatars that did not resemble them (low
402 resemblance) based on their assigned condition. Subsequently, participants visited one of two
403 cafes that differed in servicescape similarity: 1) a café with a virtual property mirroring its
404 physical property’s servicescape, and 2) a café with a virtual property differing from its
405 physical property’s servicescape (e.g., distinct interior, presence or absence of
406 facilities/amenities in the virtual property compared to the physical property). As stimuli, we
407 selected two cafés in South Korea, *SameE* and *Café Blossom*, both of which had virtual
408 properties on Zepeto. Although *SameE*’s virtual property closely resembled its physical
409 counterpart, the opposite was true for *Café Blossom* (refer to Figure 3). For each café, we
410 curated a YouTube video showcasing the servicescape, editing it into a presentation lasting
411 approximately 1 minute.

412 A total of 200 undergraduate and graduate students from Hong Kong participated in
413 the experiment, receiving bonus points as compensation. We utilized responses from 131
414 participants for further analysis, with 32 participants in the low user–avatar resemblance and
415 high servicescape similarity conditions, and 33 participants in each of the remaining three
416 conditions. To ensure our sample size was adequate, we performed a power analysis using the
417 G*Power program ($w = 0.25$, power $(1 - \beta) = 0.8$, $\alpha = 0.05$) (Faul *et al.*, 2007). The results

1
2
3 418 indicated that a minimum of 32 samples were required for each experimental condition,
4
5 419 confirming the sufficiency of our sample for further analysis.
6
7

8 420

9 10 421 *6.2. Measures and analysis*

11
12 422 Customers' offline behavioral intentions were assessed using the same four items
13
14 423 employed in Study 1. Additionally, participants' video perception, café preferences, and café
15
16 424 evaluations, measured with the items from Study 1, were considered as control variables. A 2
17
18
19 425 × 2 ANOVA with a covariate was executed to examine the hypotheses H2, H3, and H4.
20
21

22 426

23 24 427 *6.3. Results and discussion*

25
26 428 The participant demographics are detailed in the Appendix. To ensure the successful
27
28 429 manipulation of user–avatar resemblance, a comparison of responses to the manipulation
29
30 430 check question indicated successful achievement ($M_{\text{high-resemblance}} = 4.22$ vs. $M_{\text{low-resemblance}} =$
31
32 431 1.81 , $t = 25.26$, $p < 0.001$). Additionally, the manipulation of servicescape similarity was
33
34 432 confirmed to be successful, with participants in the high similarity group perceiving a higher
35
36 433 servicescape similarity than those in the low similarity group ($M_{\text{high-similarity}} = 4.15$ vs. $M_{\text{low-}}$
37
38 434 $\text{similarity}} = 2.00$, $t = 20.01$, $p < 0.001$).
39
40

41
42 435 For the main analysis, employing ANCOVA for visit intention, a significant main
43
44 436 effect of user–avatar resemblance was observed ($F(1, 130) = 44.473$, $p < 0.001$, $\eta^2 = .266$).
45
46 437 Specifically, participants using avatars resembling their appearance showed significantly
47
48 438 higher visit intentions than those using avatars that did not resemble them ($M_{\text{high-resemblance}} =$
49
50 439 3.68 , $SD = .76$ vs. $M_{\text{low-resemblance}} = 2.71$, $SD = 1.11$). These results align with prior
51
52
53 440 observations that the impact of virtual experience on individuals' offline behavior is
54
55 441 heightened when their virtual representation (e.g., avatars) resembles them in appearance
56
57
58 442 (Koulouris *et al.*, 2020; Navarro *et al.*, 2022), supporting H2.
59
60

443 Furthermore, a main effect of servicescape similarity was found ($F(1, 130) = 16.420$,
444 $p = 0.001$, $\eta^2 = .118$), with higher visit intentions in the high servicescape similarity group
445 compared to the low servicescape similarity group ($M_{\text{high-similarity}} = 3.48$, $SD = .99$ vs. $M_{\text{low-}}$
446 $\text{similarity} = 2.92$, $SD = 1.06$), supporting H3. These results are consistent with previous research
447 indicating that the impact of virtual experience on individuals' offline behavior is accentuated
448 when the virtualized environment resembles their current surroundings (Behnamnia *et al.*,
449 2020; Hernandez-Pozas and Carreon-Flores, 2019). Additionally, these findings endorse the
450 notion that the identification concept of social cognitive theory can extend to the similarity
451 between role models' appearance and their surrounding environment (Scavarelli *et al.*, 2021).

452 Finally, a significant interaction effect was observed ($F(1, 130) = 9.721$, $p < 0.001$,
453 $\eta^2 = .073$). Notably, the impact of servicescape similarity on visit intention was significant
454 when user–avatar resemblance was high, supporting H3a. As illustrated in Figure 5, the
455 difference in visit intention between the high and low servicescape similarity groups was
456 more pronounced in the high user–avatar resemblance condition.

[Figure 5]

459 7. General Discussion and Conclusion

460 7.1. Conclusions

461 This study aimed to investigate the impact of metaverse experience on customers'
462 offline behavioral intentions in the hospitality context, while also exploring two potential
463 influencing factors: user–avatar resemblance and servicescape similarity. Drawing on the
464 GLM (Buckley and Anderson, 2012) and social cognitive theory (Bandura, 1977), the
465 research hypothesized that a virtual visit to a hospitality business's property in the metaverse
466 positively influences customers' willingness to visit its physical counterpart.

1
2
3 467 Conducting two experimental studies in a café setting, Study 1 provided empirical
4
5
6 468 evidence supporting the positive impact of metaverse experience on customers' visit
7
8 469 intentions. This finding aligned with conceptual studies on metaverse marketing in the
9
10 470 hospitality and tourism industries (Gursoy *et al.*, 2022). In Study 2, the research delved into
11
12 471 the effects of user–avatar resemblance and servicescape similarity on the relationship
13
14 472 between metaverse experience and customers' visit intentions. The results were consistent
15
16 473 with prior research on the impact of virtual experiences on offline behavioral intentions,
17
18 474 indicating that the influence is contingent on the perceived similarity between avatars and
19
20 475 individuals (Koulouris *et al.*, 2020; Navarro *et al.*, 2022) and the perceived similarity
21
22 476 between the virtual environment and the individuals' surroundings (Behnamnia *et al.*, 2020;
23
24 477 Hernandez-Pozas and Carreon-Flores, 2019; Scavarelli *et al.*, 2021). Additionally, though not
25
26 478 the primary focus, supplementary analysis suggested a potential dependence of the effect of
27
28 479 servicescape similarity on the relationship between metaverse experience and customers' visit
29
30 480 intentions on user–avatar resemblance.
31
32
33
34
35
36
37

38 481 39 482 *7.2. Theoretical implications*

40 483 This research holds several theoretical implications. Firstly, it stands as a pioneering
41
42 484 empirical study delving into the marketing effects of the metaverse within the hospitality and
43
44 485 tourism domains. Although conceptual discussions on the potential impact of metaverse
45
46 486 marketing have been prevalent (Gursoy *et al.*, 2022; Kim, 2021; Koo *et al.*, 2022;
47
48 487 Mladenović *et al.*, 2023), this research addresses the call for empirical studies in the field
49
50 488 (Buhalis *et al.*, 2022; Dwivedi *et al.*, 2022). By empirically examining how metaverse
51
52 489 experience influences tourists' offline behavioral intentions in a café context, this research
53
54 490 establishes a crucial empirical baseline, aligning with observations from previous research on
55
56 491 the impact of virtual experiences on offline behavior (Wu *et al.*, 2023; Yin *et al.*, 2022).
57
58
59
60

1
2
3 492 Secondly, this research expanded the horizons of studies on experience-simulating
4
5 493 technologies by incorporating the metaverse into the discourse (Buhalis *et al.*, 2022; Gursoy
6
7 494 *et al.*, 2022; Koo *et al.*, 2022). Previous research in hospitality and tourism predominantly
8
9 495 delved into various types of experience-simulating technologies, such as augmented reality
10
11 496 (Jiang *et al.*, 2022) or virtual reality (Alyahya and McLean, 2022). Through an examination
12
13 497 of the metaverse's impact on tourists' behavioral intentions, this study posits the metaverse as
14
15 498 a promising context for exploration and suggests avenues for extending the literature on
16
17 499 virtual tourism experiences (Kim *et al.*, 2020). Additionally, while prior research has
18
19 500 embraced diverse theoretical models to elucidate the effects of experience-simulating
20
21 501 technologies on tourists' behavioral intentions, including the technology acceptance model,
22
23 502 the stimulus–organism–response model, and flow theory, this research introduces another
24
25 503 theoretical framework, the GLM and social cognitive theory, as a valuable addition to the
26
27 504 existing literature.

28
29 505 Thirdly, leveraging social cognitive theory, this study identified two key factors, user–
30
31 506 avatar resemblance and servicescape similarity, that moderate the impact of metaverse
32
33 507 experience on tourists' intentions. Aligning with prior research that underscores the
34
35 508 substantial impact of virtual experiences on behavior through heightened identification
36
37 509 (Behnamnia *et al.*, 2020; Koulouris *et al.*, 2020; Navarro *et al.*, 2022), this research
38
39 510 contributes to the literature on the effects of experience-simulating technologies on tourists'
40
41 511 behavioral intentions by introducing previously unexplored moderators. Although existing
42
43 512 literature often considers individual characteristics, such as demographics or personal
44
45 513 innovativeness, as moderators, this research highlights the significance of situational
46
47 514 characteristics as critical factors influencing the effects of experience-simulating technologies
48
49 515 on tourists' behavioral intentions (Kang *et al.*, 2022). Furthermore, despite not being the
50
51 516 primary focus, the examination of the interaction between user–avatar resemblance and
52
53
54
55
56
57
58
59
60

1
2
3 517 servicescape similarity contributes to social cognitive theory by suggesting that different
4
5 518 types of boundary conditions that enhance the impact of learning experiences on individuals'
6
7
8 519 behavioral reactions may interplay with each other.
9

10 520 Fourthly, this study explored a café context, a domain seldom addressed in the
11
12 521 literature on the impacts of experience-simulating technologies on tourists' behavioral
13
14 522 intentions. Although previous research has primarily focused on various contexts such as
15
16 523 cities, natural attractions or heritage sites, landmarks, and museums, numerous contexts
17
18 524 remain unexplored. By investigating the effects of experience-simulating technologies on
19
20 525 tourists' behavioral intentions within an uncharted context like cafés, this research
21
22
23 526 underscores the potential for further expansion of the literature in terms of diverse contexts.
24
25
26 527

28 528 *7.3. Practical implications*

30 529 First, the findings of this research can help hospitality businesses have clear
31
32 530 expectations regarding their metaverse marketing campaigns: building a virtual property in
33
34 531 the metaverse is effective in increasing customers' intentions to visit the physical property.
35
36 532 Although many hospitality businesses have considered building virtual properties in the
37
38 533 metaverse, most of them are not sure about the actual benefits of such a marketing strategy
39
40 534 (Gutt *et al.*, 2022). Such a lack of knowledge makes it difficult for a hospitality business to
41
42 535 decide whether to invest its resources in metaverse marketing. This research may provide
43
44 536 insight into this issue. The findings of Study 1 show the actual impact of metaverse
45
46 537 experience on tourists' behavioral intention and could help a hospitality business assess
47
48 538 whether the investment in building a virtual property in the metaverse is worthwhile. At the
49
50 539 same time, our findings can help hospitality businesses whose goals are not related to
51
52 540 customers' actual visits in implementing metaverse marketing. For example, takeaway- or
53
54 541 delivery-oriented cafés, which do not aim to increase customers' actual visits, could avoid
55
56
57
58
59
60

542 using their limited resources for building virtual properties in the metaverse as it would not fit
543 with such businesses' situations or goals.

544 Second, the findings of this research provide insights into what factors a hospitality
545 business should consider when choosing a metaverse platform for its marketing. Since a list
546 of metaverse platforms is now available (e.g., Roblox, Sandbox, Decentraland, and so on), a
547 hospitality business needs to target a specific platform for metaverse marketing (Park and
548 Kim, 2022). Although various factors should be taken into account in choosing a target
549 platform (e.g., user statistics or how game-oriented a platform is), a hospitality business can
550 consider other factors based on the findings of Study 2, such as whether a platform enables
551 users to customize their avatars. As mentioned in the methodology section, the currently
552 available metaverse platforms are different in terms of the extent to which the avatars can be
553 customized (Dwivedi *et al.*, 2022). The results of Study 2 indicate that a hospitality business
554 should target a metaverse platform that allows users to customize their avatars if the business
555 aims to encourage users to follow up on their virtual visit in the real world.

556 Third, the insights derived from this research offer valuable guidance to hospitality
557 businesses regarding the design of their virtual properties in the metaverse. As indicated by
558 the results of Study 2, the creation of a virtual property with a servicescape similar to its
559 physical counterpart proves to be a more effective strategy in encouraging virtual visitors to
560 transition into real visitors. Despite this evidence, some hospitality businesses, such as
561 Singapore's Millennium Hotels and Resorts, continue to adopt less effective approaches,
562 featuring virtual properties with exteriors and interiors that differ from their physical
563 establishments (Cho, 2022). For those hospitality businesses unaware of the most impactful
564 design approach for their metaverse properties, our findings serve as empirical references to
565 inform their strategies. Furthermore, taking into account the results of the additional analysis
566 (i.e., weakened effect of servicescape similarity when user–avatar resemblance is low),

1
2
3 567 businesses can tailor their approaches based on the metaverse platforms they target. In
4
5 568 instances where users cannot customize their avatars to resemble their appearance, the
6
7 569 decision of whether to align the servicescape of the virtual property with the physical
8
9 570 property may not be a critical consideration.
10
11

12 571 Finally, different design strategies can be developed according to the features of
13
14 572 metaverse platforms using the results of the interaction effects between user–avatar
15
16 573 resemblance and servicescape similarity. Study 2 found that servicescape similarity was
17
18 574 important in increasing people’s visit intention when user–avatar resemblance was high, but
19
20 575 not as critical when it was low. These findings suggest that a hospitality business should be
21
22 576 more cautious about making its virtual property similar to its physical one when targeting
23
24 577 metaverse platforms that allow avatar customization. Conversely, if the targeted metaverse
25
26 578 platforms do not allow avatar customization, a hospitality business could focus their efforts
27
28 579 on aspects other than servicescape similarity.
29
30
31
32

33 580

34 35 581 *7.4. Limitations and future research directions*

36
37 582 This research has several limitations that can guide future research directions. Firstly,
38
39 583 the exclusive participation of Hong Kong students in this study diminishes the
40
41 584 generalizability of our findings. To enhance the external validity, future research could aim to
42
43 585 diversify participant samples by including individuals from various demographics and
44
45 586 cultural backgrounds. Secondly, despite controlling for various factors that could influence
46
47 587 customers’ visit intentions, there may still be unaccounted confounding variables. Although
48
49 588 we addressed potential confounders such as participants’ perceptions of the videos and cafés,
50
51 589 their prior visits, familiarity with a given place, and knowledge about the metaverse, there
52
53 590 might be additional uncontrolled factors that could be explored in future studies. Future
54
55 591 research could provide more robust findings by considering a wider range of control factors.
56
57
58
59
60

1
2
3 592 Lastly, several aspects of the metaverse remain unexplored. This research focused on two
4
5 593 aspects of the metaverse among various factors that could affect users' behavioral intentions,
6
7
8 594 such as interaction with other users or transactions via NFTs. By investigating the unexplored
9
10 595 aspects of the metaverse, future research could complement this study by examining the
11
12 596 interrelationships between additional aspects.
